\*\*Different station than 2023's report

# Correctly calculating Utah (Richardson) chill units

In our industry, Utah chill units have been calculated from the arbitrary date of 1 May. This is incorrect as according to the model, chill units should be counted from the lowermost inflection point, i.e. the lowermost or most negative turning point, of the annual accumulated chill unit curve. In warm areas and in a warm season, the inflection point might occur much later than 1 May while in cold seasons and in cold regions, it might occur before May. The figure below illustrates how different calibrations of the Utah model can affect the reported accumulated chill.

In the figure above, the blue solid line represents year 1, where the model has been correctly calibrated, so units only begin to accumulate from the inflection point, which happens to be 1 May. The red solid line, however, indicates that in year 2, chill units are also accumulated from 1 May, but the inflection point only occurs at the end of May. The result is an accumulation of negative chill units during May of year 2, which incorrectly reduces the reported data. The red dashed line indicates the accumulated chill units in year 2 if the model is correctly calibrated to start counting chill at the actual inflection point which is at the end of May. For more information, view issue 13 of the Fresh Quarterly - <https://www.freshquarterly.co.za/publication/fresh-quarterly-issue-13-june-2021/>

Thanks to Dr Nigel Cook for contributing the data set for this chart.

Since winter 2022, we've been reporting Utah chill units from the inflection point, as specified by the model. Since the inflection points can only be determined in retrospect, we could not report on the accumulated chill units at the end of May as some regions/stations were still busy reaching their inflection points. In this report, we reported the accumulated chill units to date (30 June), the date of the inflection points as well as the re-calculated chill units for previous years so that comparison between years is possible.

# Die korrekte bepaling van Utah (Richardson) koue-eenhede

In ons bedryf is Utah koue-eenhede tot op hede vanaf die arbitrêre datum van 1 Mei bepaal. Dit is verkeerd, want volgens die model, moet koue-eenhede eers vanaf die onderste of mees negatiewe draaipunt van die jaarlikse geakkumuleerde koue-eenhede kurwe bepaal word. In warm areas en in 'n warm seisoen kan die draaipunt heelwat na 1 Mei bereik word terwyl in koue seisoene en areas dit voor Mei kan gebeur.

In die grafiek hierbo verteenwoordig die blou lyn jaar 1, waar die model korrek gekalibreer is sodat koue-eenhede eers begin akkumuleer vanaf die draaipunt, wat in die geval 1 Mei was. Die soliede rooi lyn verteenwoordig die 2de jaar waar koue-eenhede ook vanaf 1 Mei begin akkumuleer het, alhoewel die draaipunt eers teen einde Mei was. Laasgenoemde lei tot die akkumulering van negatiewe koue-eenhede gedurende Mei wat gevolglik die gerapporteerde data verkeerdlik afwaarts aanpas. Die rooi stippellyn dui die koue-eenhede aan wat geakkumuleer word gedurende jaar 2 indien die model korrek gekalibreer word sodat koue eers vanaf die werklike draaipunt begin akkumuleer. Vir meer inligting, sien uitgawe 13 van die Fresh Quarterly - <https://www.freshquarterly.co.za/publication/fresh-quarterly-issue-13-june-2021/>.

Dankie aan Dr Nigel Cook vir die bydra tot die datastel vir die grafiek.

Sedert winter 2022 het ons Utah koue-eenhede korrek gerapporteer volgens die model, vanaf die draaipunt. Aangesien die draaipunte net terugskouend bepaal kan word, kon ons nie die ge-akkumuleerde koue eenhede teen einde Mei rapporteer nie omdat sommige areas/stasies nog nie hul draaipunte bereik het nie. In die verslag word die ge-akkumuleerde koue-eenhede tot en met 30 Junie gerapporteer asook die datums van die draaipunte en die herberekende koue-eenhede van vorige jare om vergelyking tussen jare moontlik te maak.

# Accumulated Richardson cold units until 30 June 2021 - 2024
